Cheat Sheet: Python Data Structures Part-2

Dictionaries

Package/Method	Description	Code Example Example:
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces {}.	1. 1 2. 2 1. dict_name = {} #Creates an empty dictionary 2. person = { "name": "John", "age": 30, "city": "New York"} Copied!
Accessing Values	You can access the values in a dictionary using their corresponding keys.	<pre>Syntax: 1. 1 1. Value = dict_name["key_name"] Copied! Example: 1. 1 2. 2 1. name = person["name"] 2. age = person["age"] Copied! Syntax:</pre>
Add or modify	Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	<pre>1. 1 1. dict_name[key] = value Copied! Example: 1. 1 2. 2 1. person["Country"] = "USA" # A new entry will be created. 2. person["city"] = "Chicago" # Update the existing value for the same key</pre>
del	Removes the specified key-value pair from the dictionary. Raises a KeyError if the key does not exist.	Copied! Syntax: 1. 1 1. del dict_name[key] Copied! Example: 1. 1 1. del person["Country"] Copied! Syntax:
update()	The update() method merges the provided dictionary into the existing dictionary, adding or updating key-value pairs.	<pre>1. 1 1. dict_name.update({key: value}) Copied! Example: 1. 1</pre>
clear()	The clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	<pre>1. dict_name.clear() Copied!</pre>
		<pre>Example: 1. 1 1. grades.clear()</pre>

18/09/2024, 17:26 about:blank

```
Copied!
                                                                   Example:
                                                                     1. 1
                  You can check for the existence of a key in a
                                                                     2. 2
key existence
                  dictionary using the in keyword
                                                                     1. if "name" in person:
                                                                             print("Name exists in the dictionary.")
                                                                   Copied!
                                                                   Syntax:
                                                                     1. 1
                                                                     1. new_dict = dict_name.copy()
                                                                    Copied!
                  Creates a shallow copy of the dictionary. The new
                  dictionary contains the same key-value pairs as
copy()
                                                                   Example:
                  the original, but they remain distinct objects in
                  memory.
                                                                     1. new_person = person.copy()
2. new_person = dict(person) # another way to create a copy of dictionary
                                                                   Copied!
                                                                   Syntax:
                                                                     1. keys_list = list(dict_name.keys())
                                                                   Copied!
                  Retrieves all keys from the dictionary and
keys()
                  converts them into a list. Useful for iterating or
                  processing keys using list methods.
                                                                   Example:
                                                                     1. 1
                                                                     1. person_keys = list(person.keys())
                                                                   Copied!
                                                                   Syntax:
                                                                     1. 1
                                                                     1. values_list = list(dict_name.values())
                  Extracts all values from the dictionary and
                                                                   Copied!
values()
                  converts them into a list. This list can be used for
                  further processing or analysis.
                                                                   Example:
                                                                     1. 1
                                                                     1. person_values = list(person.values())
                                                                   Copied!
                                                                   Syntax:
                                                                     1. 1
                                                                     1. items_list = list(dict_name.items())
                  Retrieves all key-value pairs as tuples and
                                                                   Copied!
items()
                  converts them into a list of tuples. Each tuple
                                                                   Example:
                  consists of a key and its corresponding value.
                                                                     1. 1
                                                                     1. info = list(person.items())
                                                                   Copied!
```

Sets

Package/Method	1 Description	Code Example
		Syntax:
		1. 1
add() clear()	Elements can be added to a set using the `add()` method. Duplicates are automatically removed, as sets only store unique values. The `clear()` method removes all elements from the set, resulting in an empty set.	<pre>1. set_name.add(element)</pre>
		Copied!
		Example:
		1. 1
		<pre>1. fruits.add("mango")</pre>
		Copied!
		Syntax:
	It updates the set in-place.	1. 1
		<pre>1. set_name.clear()</pre>

about:blank 2/4

18/09/2024, 17:26 about:blank

Copied! Example: 1. 1 1. fruits.clear() Copied! Syntax: 1. 1 1. new_set = set_name.copy() Copied! The `copy()` method creates a shallow copy of the set. Any modifications to the copy() copy won't affect the original set. Example: 1. 1 1. new_fruits = fruits.copy() Copied! Example: 1. 1 2. 2 A set is an unordered collection of unique elements. Sets are enclosed in curly Defining Sets braces `{}`. They are useful for storing distinct values and performing set 1. empty_set = set() #Creating an Empty
2. Set fruits = {"apple", "banana", "orange"} operations. Copied! Syntax: 1. 1 1. set_name.discard(element) Copied! Use the 'discard()' method to remove a specific element from the set. Ignores if discard() the element is not found. Example: 1. 1 1. fruits.discard("apple") Copied! Syntax: 1. 1 1. is_subset = set1.issubset(set2) Copied! The `issubset()` method checks if the current set is a subset of another set. It issubset() returns True if all elements of the current set are present in the other set, Example: otherwise False. 1. is_subset = fruits.issubset(colors) Copied! Syntax: is_superset = set1.issuperset(set2) The `issuperset()` method checks if the current set is a superset of another set. It Example: returns True if all elements of the other set are present in the current set, issuperset() otherwise False. 1. 1 1. is_superset = colors.issuperset(fruits) Copied! Syntax: 1. removed_element = set_name.pop() Copied! The 'pop()' method removes and returns an arbitrary element from the set. It pop() raises a `KeyError` if the set is empty. Use this method to remove elements when Example: the order doesn't matter. 1. removed_fruit = fruits.pop() Copied! remove() Use the 'remove()' method to remove a specific element from the set. Raises a Syntax: `KeyError` if the element is not found. 1. 1 1. set_name.remove(element) Copied!

18/09/2024, 17:26 about:blank

Perform various operations on sets: `union`, `intersection`, `difference`,

Example:

1. fruits.remove("banana")

Copied!

Syntax:

1. 1 2. 2 3. 3 4. 4

1. union_set = set1.union(set2)

2. intersection_set = set1.intersection(set2)

3. difference_set = set1.difference(set2)
4. sym_diff_set = set1.symmetric_difference(set2)

Copied!

Example:

1. 1 2. 2 3. 3 4. 4

1. combined = fruits.union(colors)

common = fruits.intersection(colors)
 unique_to_fruits = fruits.difference(colors)
 sym_diff = fruits.symmetric_difference(colors)

Copied!

Syntax:

1. set_name.update(iterable)

Copied!

Example:

1. 1

1. fruits.update(["kiwi", "grape"])

Copied!

The `update()` method adds elements from another iterable into the set. It update()

maintains the uniqueness of elements.

`symmetric difference`.
